

## Mixing and un-mixing by incompressible flows

Yao Yao, Georgia Tech

In this talk, we consider the questions of efficient mixing and un-mixing by incompressible flows, under the constraint that the  $W^{1,p}$  Sobolev norm of flow is uniformly bounded in time. We construct some explicit flows to show that for any bounded initial density, it can be mixed to scale  $\epsilon$  in time  $O(|\log(\epsilon)|)$  for  $p < (3 + \sqrt{5})/2$  and in time  $O(|\log(\epsilon)|^{1/3})$  for  $p \geq (3 + \sqrt{5})/2$ , where the constants in both results are independent of the initial data. Known lower bounds show that this rate is optimal for  $p$  between 1 and  $(3 + \sqrt{5})/2$ . For un-mixing, we show that any set which is mixed to scale  $\epsilon$  but not much more than that can be un-mixed to a rectangle of the same area (up to a small error) in time  $O(|\log \epsilon|^2)$ .

This is a joint work with Andrej Zlatoš.
