

## **From Kaczmarz algorithm to minimal energy problems**

Xuemei Chen, University of San Francisco

The Kaczmarz algorithm is an iterative method to solve linear systems. It falls into the category of row action methods. When the rows are randomized, it takes the form of stochastic gradient descent. We are interested in the particular distribution that the rows can take in order to optimize the convergence rate, which has connections to minimal energy problems, in both discrete and continuous settings.
