- The irreducible modules for the symmetric groups over \mathbb{C} are labelled by partitions.
- Over a field F of characteristic p , the irreducible modules of the tower of group algebras are labelled by p -regular partitions.
- Take a element ξ in a field k with $1 + \xi + \dots + \xi^{e-1} = 0$. For the tower of cyclotomic Hecke algebras over K , the irreducible modules are labelled by e -regular multipartitions.

The problem: For $e > 2$, we have only a recursive algorithm for constructing e -regular multipartitions.

Affine Lie Algebras of Type A

- \mathcal{G} - an affine Lie algebra of type A,
- Dynkin diagram a circle,
- $\Lambda_0, \Lambda_1, \dots, \Lambda_\ell$ - fundamental weights, $\ell = e - 1$
- $\alpha_0, \alpha_1, \dots, \alpha_\ell$ - simple roots,
- $\delta = \sum \alpha_i$ - the null root.
- $\mathbb{Q}_+ = \{\alpha \mid \alpha = \sum c_i \alpha_i\}$, with content $(c_0, c_1, \dots, c_\ell)$,
- A corank 1 Cartan matrix

$$A = \begin{bmatrix} 2 & -1 & 0 & \dots & 0 & -1 \\ -1 & 2 & -1 & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & -1 & 2 & -1 \\ -1 & 0 & \dots & 0 & -1 & 2 \end{bmatrix}$$

Kashiwara crystals

- Let $e_i, f_i, h_i, i = 0, 1, \dots, \ell, c$ be a Chevalley basis
- Let $\Lambda = a_0\Lambda_0 + \dots + a_\ell\Lambda_\ell, a_i \in \mathbb{Z}_+$
- Let $V(\Lambda)$ be a highest weight representation generated by the f_i from u_θ of weight Λ
- Let $P(\Lambda)$ be the sets of weights of weight spaces of $V(\Lambda)$
- Let $\max(\Lambda)$ be the set of weights $\eta \in P(\Lambda)$ such that $\eta + \delta \notin P(\Lambda)$.

A Kashiwara crystal $B(\Lambda)$ is

- a labeling of the basis of $V(\Lambda)$
- operations \tilde{e}_i and \tilde{f}_i ,
- functions ϕ_i, ϵ_i measuring the distance to the end of the local i -string.

There are three important versions of the Kashiwara crystal in type A:

- by e -regular multipartitions
- by Littelmann paths,
- and by canonical basis elements, in a space called Fock space, with coefficients which are v -polynomials

Our general research program concerns the combinatorial relations among all three, but for this talk, we focus on the possibility of passing directly between the e -regular multipartitions and the canonical basis elements. In the process, we also found a result on the Morita equivalence classes of cyclotomic Hecke algebras.

We get the *reduced* crystal $[AS]$ with vertices $P(\Lambda)$ by adding edges wherever there is an edge in the underlying Kashiwara crystal, where we take all i -strings parallel to each other. The weights in $P(\Lambda)$ are of the form $\lambda = \Lambda - \alpha$ for some $\alpha \in Q_+$. The highest-weight representation being integrable, all i -strings are of finite length. To each vertex of $P(\Lambda)$ we associate

- The content (c_0, \dots, c_ℓ) of $\alpha = c_0\alpha_0 + \dots + c_\ell\alpha_\ell$
- The defect $\text{def}(\lambda) = (\Lambda \mid \alpha) - \frac{1}{2}(\alpha \mid \alpha)$
- The hub $\theta = (\theta_0, \dots, \theta_\ell)$, where $\theta_i = \langle h_i, \lambda \rangle$

The vertices of defect zero are those equivalent to Λ under the action of the Weyl group W .

Reduced crystal, $e = 2, \Lambda = 3\Lambda_0 + 3\Lambda_1$, with hubs

Chuang and Rouquier [CR] categorification:

- $V(\Lambda) \Leftarrow \bigoplus \text{Mod}(H_n^\Lambda)$, $n = 0, 1, 2, \dots$
- $e_i, f_i \Leftarrow$ restriction and induction functors E_i, F_i
- Weight spaces \Leftarrow blocks,
- $s_i \in W \Leftarrow$ derived equivalences,
- s_i acting on end-points of i -string \Leftarrow Morita equivalence
- $b \in B(\Lambda) \Leftarrow$ simple modules of H_n^Λ

The simplest but best known example is for $r = 1$, $\Lambda = \Lambda_0$, over a field of characteristic e , where the simple modules of the symmetric groups correspond to e -regular partitions.

The Fundamental Region

We want to show that for a given defect d there are only a finite number of Morita equivalence classes of cyclotomic Hecke algebras, relying on categorification and using combinatorics. So far we can do this for ranks $e = 2, 3$. We start with the following theorem.

Theorem (Barshavsky, Fayers, S., 2013) For any $\eta = \Lambda - \sum_{i=0}^{\ell} b_i \alpha_i$ there is a unique s such that

$$\eta - s\delta \in \max(\Lambda)$$

The proof, which is given for any type of affine Lie algebra, depends on finding a fundamental region in $P(\Lambda)$ from which every element of $\max(\Lambda)$ can be reached by transformations in the normal abelian subgroup T in the decomposition of the Weyl group as

$$W = T \rtimes W^\circ$$

The Fundamental Region

The elements of T are transformations of the form

$$t_\alpha(\zeta) = \zeta + r\alpha - ((\zeta|\alpha) + \frac{1}{2}(\alpha|\alpha)r)\delta$$

By the theorem in the previous slide, every vertex in $\max(\Lambda)$ is equivalent by the action of the Weyl subgroup T to a point in the fundamental region and every defect is congruent mod r to a defect in the fundamental region. Thus the elements of $\max(\Lambda)$ correspond one-to-one to points of the integral lattice generated by $\alpha_1, \dots, \alpha_\ell$.

On a string, $\text{def}(\lambda - k\alpha_i)$ is parabolic in k , so the defects rise to the center, and for a string of length c there can be no defect less than c except at the ends. Lengths of i -strings are determined by θ_i

The reduced crystal for $e = 3, \Lambda = \Lambda_0 + \Lambda_1 + \Lambda_2$

Proposition

For any defect d in a rank 2 or 3 crystal, there is a degree $N(d)$ such that every occurrence of that defect in degree more than $N(d)$ is at the end of a string to a vertex of lower degree.

Proof.

Case $e = 3$: Let $c = r + 2d$. Let N be the maximal degree occurring in a triangle $[c, -d, -d]$, $[-d, c, -d]$, $[-d, -d, c]$. Every hub on or outside the triangle contains a negative θ_i with $\theta_i \leq -d$. Every vertex inside the triangle has degree lower than $N + 1$. Let \bar{d} be the residue of d mod r and set $N(d) = N + 1 + (d - \bar{d})$. Thus every $b \in B(\Lambda)$ of defect d lies on a string leading to a lower degree of length $\geq d$. Since a basis element of defect d cannot be internal, it is at the end of a this string.

The canonical basis elements correspond to e -regular multipartitions. In order to generate the e -regular multipartitions, we must choose an ordering of the fundamental weights in Λ ,

$$\Lambda = \Lambda_{k_1} + \cdots + \Lambda_{k_r}$$

We will follow Mathas in [M] in requiring $k_1 \leq k_2 \leq \cdots \leq k_r$, where the number of terms, r , in the sum is the level. We can then summarize by setting

$$\Lambda = a_0 \Lambda_0 + \cdots + a_\ell \Lambda_\ell$$

The Young diagram of a defect 0 weight λ will be represented by $Y(\lambda)$. If the m -th partition of λ is nonempty, then we associate to each node in the Young diagram a residue, where the node (i, j) is given residue

$$k_m + j - i$$

Involutions of multipartitions

In [Fa], Fayers describes two involutions on the multipartitions:

Definition

If $\lambda = (\lambda^1, \dots, \lambda^r)$ is a multipartition of rank e and level r , then the *conjugate* λ' of λ is given by $\lambda' = (\lambda^{r'}, \dots, \lambda^{1'})$, where $\lambda^{i'}$ is the transposed partition of λ^i , corresponding to reflection of the Young diagram in the main diagonal.

Definition

If $\lambda = (\lambda^1, \dots, \lambda^r)$ is a multipartition of rank e and level r for $\Lambda = \Lambda_{k_1} + \dots + \Lambda_{k_r}$, then the *diamond* λ^\diamond of λ is a multipartition in the crystal for $\hat{\Lambda} = \Lambda_{-k_r} + \dots + \Lambda_{-k_1}$, whose path is obtained from a path giving λ by replacing each residue by minus that residue.

- $\mathcal{U} = \mathcal{U}_v(\hat{\mathfrak{sl}}(e))$: quantum enveloping algebra over $\mathbb{Q}(v)$
- $[n]_v = v^{n-1} + v^{n-3} + \dots + v^{-(n-3)} + v^{-(n-1)}$.
- Generators: e_i, f_i, h_i for $i \in I = \mathbb{Z}/\mathbb{Z}e$ and a central c .
- If $\Lambda = \Lambda_{k_1} + \dots + \Lambda_{k_r}$, set $s = (k_1, \dots, k_r)$.

The Fock space \mathcal{F}^s is a space with basis given by multipartitions consisting of r partitions. An addable i -node \mathfrak{n} is a node outside λ such that if added it would give a multipartition $\lambda^{\mathfrak{n}}$ and would have residue i . A removable i -node \mathfrak{m} inside a multipartition μ is a node at the end of a row or column which would give a multipartition $\mu_{\mathfrak{m}}$ if removed.

Fock Space

The quantum enveloping algebra $\mathcal{U}_v(\hat{\mathfrak{sl}}(e))$ acts on the Fock space by determining actions for the elements of the Chevalley basis, as follows:

- For an addable node, define $N(\mathfrak{n}, i) = \#\{\text{addable } i\text{-nodes above } \mathfrak{n}\} - \#\{\text{removable } i\text{-nodes above } \mathfrak{m}\}$ and set

$$f_i(\lambda) = \sum_{\mathfrak{n}} v^{N(\mathfrak{n}, i)} \lambda^{\mathfrak{n}}.$$

- For a removable node, define $M(\mathfrak{m}, i) = \#\{\text{addable } i\text{-nodes below } \mathfrak{m}\} - \#\{\text{removable } i\text{-nodes below } \mathfrak{m}\}$.

$$e_i(\mu) = \sum_{\mathfrak{m}} v^{M(\mathfrak{m}, i)} \mu_{\mathfrak{m}}.$$

The divided powers are $e_i^{(k)}$ and $f_i^{(k)}$ and they are given by dividing by the quantum factorials $[k]_v!$. We define $\mathcal{F}_{\mathcal{A}}^s$ to be the subalgebra of \mathcal{F}^s generated by the divided powers from the highest weight vector over \mathcal{A} , where coefficients lie in the algebra \mathcal{A} of Laurent polynomials in v with integral coefficients. In addition, there is an involution of the quantum enveloping algebra called the bar-involution which fixes e_i , f_i and h_i , but interchanges v and v^{-1} .

For each e -regular multipartition μ , there is an element $G(\mu)$ of the Fock space $\mathcal{F}_{\mathcal{A}}^s$ that is invariant under the bar involution. and these are called the canonical basis elements. The action of the Chevalley basis elements e_i and f_i on these canonical basis elements is induced from their action on the basis elements of the Fock space. We write

$$G(\mu) = \sum_{\lambda \in P^r} d_{\lambda\mu}(v) \lambda$$

Definition

For a sequence S chosen from a two element ordered set $\{0, 1\}$, the number of inversions, $\text{Inv}(S)$, is the sum of the number of elements 0 appearing before each element 1.

Definition

The *shape* of a canonical basis element is the number of multipartitions, counting repetitions, for each power of v .

Definition

A vertex v in the reduced crystal is i -external if $\tilde{e}_i(b)$ is zero for every element of $B(\Lambda)$ with the weight corresponding to v .

External canonical basis elements

Lemma

Let μ be an e -regular multipartition for an i -external vertex of the reduced crystal with i -string of length c . Let $\mathcal{S}(c, k)$ be the set of sequences of length c with k copies of 1 and $c - k$ copies of 0. For any $S \in \mathcal{S}(c, k)$, let λ^S be the multipartition obtained by adding each node corresponding to a 1. If every multipartition occurring in $G(\lambda)$ has c of addable i -nodes and no removable nodes, then

$$\tilde{f}_i^{(k)}(G(\mu)) = \sum_{S \in \mathcal{S}(c, k)} \sum_{\lambda \in Pr} d_{\lambda\mu} v^{\text{Inv}(S)} \lambda^S$$

For $k = c$ and S the unique sequence with all copies of 1,

$$G(\mu^S) = \sum_{\lambda \in Pr} d_{\lambda\mu} \lambda^S$$

In Theorem 2.1 of [Fa], Fayers proves that if $w(\mu)$ is the defect of an e -regular multipartition μ , then

$$\hat{d}_{\lambda'\mu^\diamond} = v^{w(\mu)} d_{\lambda\mu}(v^{-1}).$$

This theorem involves constructing two distinct crystals and comparing them. Instead, let $\Lambda = a\Lambda_0 + a\Lambda_1 + \cdots + a\Lambda_\ell$ be symmetric. By using Fayer's \diamond involution, followed by a reshuffling of the tuple s used in the definition of the Fock space, we find that for any path, the path we get by exchanging k with $\ell - k$ has canonical basis elements which by symmetry have the same shape and by the \diamond involution are thus symmetric.

Let us take a completely symmetric crystal,

$$\Lambda = a\Lambda_0 + a\Lambda_1 + \cdots + a\Lambda_\ell.$$

- The canonical basis elements of a symmetric crystal have a symmetric shape.
- For $e = 2$, we can give formulae for the canonical basis elements of all weights with defect $a(k - a)$
- For $e = 3$, we can give formula for canonical basis elements with for weights $\lambda - k\alpha_i$ with $0 \leq k \leq a$. Every block of the cyclotomic Hecke algebra is Morita equivalent to one of a finite set of blocks of degree less than some bound $N(d)$ and the canonical basis elements are easily obtained from those of this finite set.

The Littelmann paths for a given \mathcal{G} and Λ can be generated in Sagemath using the function `CrystalOfLSPaths()` written by Mark Shimozono and Anne Schilling. In addition, Travis Scrimshaw implemented an algorithm of Matt Fayers to calculate the canonical basis, named `FockSpace()`.

Our own modification computes the following for a basis element $b \in B(\Lambda)$:

- The multipartition
- The Littelmann path and, optionally, the corner-points
- The canonical basis element
- The set of paths in the reduced crystal leading to b
