Near Substitutes and Equilibria with Indivisibilities
Rakesh Vohra, University of Pennsylvania

We use the demand type framework of Baldwin and Klemperer to formalize what it means for preferences (both quasi-linear and otherwise) to be near substitutes over bundles of indivisible goods. This allows us to identify prices at which the excess demand for each good is bounded by a parameter related to the degree with which preferences depart from substitutes but independent of the size of the economy.
