Spectral sets and derivatives of the psd cone
Kummer, Mario - TU Berlin

A spectrahedron is the solution set to a linear matrix inequality. Consider a spectrahedral cone $K$ in $n$-space which is symmetric with respect to permuting the coordinates. According to an observation by Bauschke, Güler, Lewis and Sendov the set $S(K)$ of all symmetric $n \times n$ matrices, whose spectrum is in $K$, is a hyperbolicity cone. We give a representation theoretic sufficient condition on $K$ for $S(K)$ being a spectrahedral cone. Applying this to Brändén's spectrahedral representation of elementary symmetric polynomials yields a spectrahedral representation of all derivative relaxations of the cone of positive semidefinite matrices.
