Macroscopic scale: the empirical spectral measure

Suppose that *M* is an $n \times n$ random matrix with eigenvalues $\lambda_1, \ldots, \lambda_n$.

The empirical spectral measure μ of *M* is the (random) measure

$$\mu := \frac{1}{n} \sum_{k=1}^{n} \delta_{\lambda_k}.$$

Wigner's Theorem

Wigner's Theorem

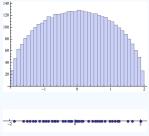

For each $n \in \mathbb{N}$, let $\{Y_i\}_{1 \le i}, \{Z_{ij}\}_{1 \le i < j}$ be independent collections of i.i.d. random variables, with

 $\mathbb{E} Y_1 = \mathbb{E} Z_{12} = 0 \qquad \mathbb{E} Z_{12}^2 = 1 \qquad \mathbb{E} Y_1^2 < \infty.$

Let M_n be the symmetric random matrix with diagonal entries Y_i and off-diagonal entries Z_{ij} or Z_{ji} .

The empirical spectral measure μ_n of $\frac{1}{\sqrt{n}}M_n$ is close, for large *n*, to the semi-circular law:

$$\frac{1}{2\pi}\sqrt{4-x^2}\mathbb{1}_{|x|\leq 2}dx.$$

Typical vs. average

In ensembles with the concentration property, $W_1(\mu_n, \nu)$, this means

$$\mathbb{P}[W_1(\mu_n,\nu) > \mathbb{E}W_1(\mu_n,\nu) + t] \le Ce^{-cN^2t^2}$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

In ensembles with the concentration property, $W_1(\mu_n, \nu)$, this means

$$\mathbb{P}[W_1(\mu_n,\nu) > \mathbb{E}W_1(\mu_n,\nu) + t] \le Ce^{-cN^2t^2}$$

To show $W_1(\mu_n, \nu)$ is typically small, it's enough to show that $\mathbb{E}W_1(\mu_n, \nu)$ is small.

Average distance to average

One approach: consider the stochastic process

$$X_{f}:=\int f d\mu_{n}-\mathbb{E}\int f d\mu_{n}.$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

Average distance to average

One approach: consider the stochastic process

$$X_{\mathsf{f}} := \int \mathsf{f} \mathsf{d} \mu_{\mathsf{n}} - \mathbb{E} \int \mathsf{f} \mathsf{d} \mu_{\mathsf{n}}.$$

Under the concentration hypothesis, ${X_f}_f$ satisfies a sub-Gaussian increment condition:

$$\mathbb{P}\left[|X_f - X_g| > t\right] \leq 2e^{-\frac{cn^2t^2}{|t-g|_L^2}}$$

Dudley's entropy bound together with approximation theory, truncation arguments, etc., can lead to a bound on

$$\mathbb{E}W_1(\mu_n,\mathbb{E}\mu_n)=\mathbb{E}\left(\sup_{|f|_L\leq 1}X_f\right).$$

 $\begin{array}{c} \text{concentration} \\ \text{of } \mathcal{N}_{[0,\theta]} \end{array}$

If *U* is a random unitary matrix, then *U* has eigenvalues

 $\{e^{i\theta_k}\}_{k=1}^N,$ for $0 \le \theta_1 < \theta_2 < \cdots < \theta_N < 2\pi.$ We define the predicted locations to be

 $\{e^{\frac{2\pi ik}{N}}\}_{k=1}^N.$

 $\underset{of \ \mathcal{N}_{[0,\theta]}}{\text{concentration}}$

where ν is the uniform distribution on $\mathbb{S}^1 \subseteq \mathbb{C}$.

 \leftarrow concentration of $e^{i\theta_k}$ about e^{ik}
